## Key Words

Ion channels • Pancreas cancer • Oncogenesis

## Abstract

The current basis of systemic treatment for pancreas cancer involves cytotoxic chemotherapy. Despite newer regimens, overall survival remains poor and this dilemma is further compounded by a lack of effective, novel therapeutic targets. Another challenge in treating pancreas cancer is the complex tumor microenvironment, which contains regulatory T cells, myeloid derived suppressor cells, and tumor associated macrophages that forms a barrier to standard therapies. Intracellular ion channels are ubiquitously expressed in all cells and their role in carcinogenesis is increasingly becoming elucidated. They play an integral role in each of the six "Hallmarks of Cancer" and are potential novel prognostic biomarkers and therapeutic targets for pancreas cancer. Although examined in various hematologic and gastrointestinal malignancies, there are limited data examining the prognostic role of specific ion channels in pancreas ductal adenocarcinoma. This review focuses on chloride (CLCA-1, CLIC1, CLIC3), calcium (TRPM7, TRPM8), and potassium (Kir3.1, KCa3.1, Kv11.1, Kv1.3) channels in pancreas cancer.

## Introduction

Despite the development of more effective systemic therapies and advances in surgical technology, pancreas cancer remains one of the deadliest gastrointestinal malignancies. With an increasing incidence, it is expected to affect 56,770 patients in the US in 2019 and has moved to the third leading cause of cancer related death [1]. Five year overall survival (OS) remains a dismal 9.3% for all stages and even for those patients who present with localized disease, it is only 37.4% [2]. This poor prognosis is attributed to lack of effective screening, late presentation, and high recurrence rates [3]. Of the numerous pancreas cancer histologies, pancreas ductal adenocarcinoma (PDAC) is the most common and will be the focus of this review.

Surgery is the only curative treatment for pancreas cancer, however, systemic therapy is still recommended as the majority of patients have micrometastatic disease at the time of presentation [4]. The CLUSTER study examining circulating tumor cells (CTC) in patients

with resectable pancreas cancer found that >95% of patients had CTCs in peripheral blood samples [3]. This study is one of many showing that patients with seemingly localized pancreas cancer are at high risk of developing distant metastases. The most effective adjuvant systemic therapy regimen, based on published randomized data, is modified FOLFIRINOX. Compared to gemcitabine, FOLFIRINOX was found to have an astonishing median OS of 54.4 mo compared to 35.0 mo [5]. However, despite this newer cytotoxic chemotherapy regimen for PDAC, survival remains poor. One of challenges in treating pancreas cancer is due to the presence of a dense stromal reaction. This stroma contains a multitude of different cell types that result in drug resistance and pro-growth/metastatic signals. Unfortunately, newer drugs specifically targeting the pancreas stroma have resulted in worse outcomes in phase I clinical trials [6].

One of the most exciting treatment strategies to emerge over the last decade has been immunotherapies. Targeting the immune system to fight cancer has shown dramatic results in malignancies, such as melanoma. However, similar benefits have not been seen in pancreas cancer due in part to low levels of microsatellite instability and resistance provided by the stroma [7]. Given the lack of new treatments and reliance on still decades old cytotoxic systemic therapies, new and innovative targets are needed.

## **Ion Channels in Cancer**

Ion channels are an integral part of normal cellular processes regulating cell membrane potential, signal transduction, and proliferation. They are transmembrane proteins found in both the intra- and extracellular cellular compartments that control flow of ions across the cell membrane [8]. The two general categories of ion channels are voltage gated and ligand gated channels. Voltage gated channels are classified based on the ions that passed through them while ligand gated are described based on the ligand that controls the channel [9]. Although ion channels in the plasma membrane have been extensively studied, intracellular ion channels in mitochondria, endoplasmic reticulum, Golgi apparatus, nucleus, lysosomes, endosomes, and peroxisomes are only slowly coming to light [10]. What roles these intracellular channels specifically have in carcinogenesis is only beginning to be understood [11-14].

Hanahan and Weinberg described in their seminal "The Hallmarks of Cancer", that there are six essential processes whereby cancer cells acquire the ability to grow and propagate. They are 1) self-sufficiency in growth signals, 2) insensitivity to antigrowth signals, 3) evading apoptosis, 4) limitless replicative potential, 5) sustained angiogenesis, and 6) tissue invasion and metastasis [15]. Ion channels are intimately involved in all of these oncogenic processes and Prevarskaya et al. eloquently described what roles specific channels have in each process [16]. They further describe that dysfunction of certain channels that results in a malignant phenotype can be considered an "oncochannelopathy" [8]. Despite the extensive role ion channels play, targeting these ubiquitously expressed proteins can be challenging, particularly since normal cells are at risk of substantial toxicity. Strategies to mitigate this risk involves creating a prodrug that can only be activated by cancer cells and targeting channels that are uniquely overexpressed in tumor cells [16].

In pancreas cancer, given the paucity of novel therapeutic targets, ion channels present an untapped field for further study.

## Ion Channels in Pancreas Cancer

As mentioned previously, pancreas cancer presents unique challenges as systemic regimens that are quite effective in other malignancies do not have the same efficacy in pancreas cancer. One of the reasons for this is the dense desmoplastic reaction or stroma associated with pancreas cancer. This stroma can occupy >80% of the tumor mass, creating a physical barrier to drug delivery and impairs activation of the immune system [17, 18]. Once thought to be an immune desert, PDAC is rich in immune cells, however, the majority are immunosuppressive rather than activating. Regulatory T cells, myeloid derived suppressor cells, and tumor associated macrophages within the stroma work by reducing antigen presentation, inducing T cell apoptosis, and facilitate transition from a pro- to anti-inflammatory state [18]. Numerous clinical trials are underway targeting various components of the stroma. However, of the trials that have completed, the data has not shown the same efficacy that was seen in preclinical studies [19-21]. Ion channels provide an alternative therapeutic target in pancreas cancer that is being increasingly evaluated.

### Chloride Channels

Chloride channels are self-assembling proteins that regulate cell adhesion, control of the cell cycle, osmoregulation, lipid metabolism, mitochondrial function, cell polarity, and apoptosis [22, 23]. Studies in PDAC have found that not only is there differential expression, but also an association with cancer growth and spread. The Chloride Channel Accessory (CLCA) protein, are self-cleaving proteins that activate Ca-dependent Cl<sup>-</sup> channels [24]. CLCA specifically interacts with  $\beta$ 4 integrins and helps facilitate metastatic spread [22]. Of the three functional subtypes, CLCA-1 has been implicated in cell differentiation and carcinogenesis. In colorectal cancer, under expression of this protein has been associated with higher histologic grade, lymph node metastasis, and worse overall survival [25]. Proteomic analysis by *Hu et al.* examining potential prognostic biomarkers in PDAC showed that CLCA-1 was downregulated by 20-fold compared to normal tissue [26]. When protein expression was then examined in 140 patients that underwent resection, low CLCA-1 expression was associated with worse disease free survival (11.9 vs 17.5 months,  $p=0.042$ ) [24]. On multivariate Cox regression analysis, low CLCA-1 expression remained independently predictive of poorer survival [24]. CLCA-1 also has a potential role in cystic lesions of the pancreas.

PDAC can arise from cystic lesions of the pancreas. The two most commonly implicated are intraductal papillary mucinous neoplasms (IPMNs) and mucinous cystic neoplasms (MCNs). These lesions are considered premalignant and have varying malignant potential, with not all lesions harboring cancer. They are often found incidentally, providing a potential opportunity for early detection and management. However, deciding which lesions require resection, because of underlying high-grade dysplasia or invasive cancer, remains challenging. Cyst fluid sampling and testing for specific protein mutations is an area of active investigation. Studies examining biomarkers in cyst fluid using mass spectroscopy have found that CLCA-1 is secreted into pancreatic cyst fluid [27]. Furthermore, they found that the presence of CLCA-1 carried a 100% positive predictive value and 87% negative predictive value for having high-grade dysplasia/invasive cancer [27]. These data suggest that CLCA-1 is not only a potential prognostic biomarker but also a possible therapeutic target in PDAC.

Chloride Intracellular Channels (CLICs) are self-assembling anion channels implicated in regulation of the cell cycle, cell adhesion, migration, tumor invasiveness, and apoptosis [22, 23, 28-30]. These proteins are unique in that they can exist in a soluble form and as an integral membrane protein [23]. CLIC1 was examined in patients with resected PDAC and when compared to adjacent normal tissue, tumor samples had significantly higher protein expression (67.1% vs 25.7%,  $p<0.001$ ). Furthermore, over expression was associated with higher histologic grade, tumor size, and worse overall survival (HR 5.822, 95% CI 1.329-15.628,  $p=0.016$ ) [28]. Another CLIC, CLIC3, has also been implicated in PDAC. Studies examining CLIC3 expression in resected PDAC specimens, as well as in precursor lesions called pancreatic intraepithelial neoplasms (PanINs), found overexpression in PDAC

specimens [31]. However, in PanIN lesions, CLIC3 expression increased with greater degrees of dysplasia compared to lesions with well-organized epithelia [31]. When examining survival, high CLIC3 expression was the strongest independent predictor of worse OS (HR 4.81, 95%CI 1.86-12.3,  $p=0.001$ ) [31]. CLIC3's role in tumor invasiveness is thought to be through a Rab25 dependent mechanism, which is essential for integrin recycling. Taken together, these data show the importance of chloride channels in PDAC invasiveness and progression.

### *Calcium Channels*

Calcium is one of the most important second messengers in cellular processes. As such, regulation of calcium plays an integral role in carcinogenesis. One of the calcium channel super-families that has a particular role in PDAC is the transient receptor potential (TRP) group. These proteins form either homo- or heterotetramers and are subdivided into seven subfamilies (classical or canonical, melastatin, ankyrin, vanilloid, polycystin, NOMP-C homologues, and mucolipin) [32].

TRPM7, of the melastatin subfamily, has been shown to have a key role in development of the exocrine pancreas in zebrafish [33]. This protein was also examined in patients with resected PDAC and compared to normal controls, TRPM7 was overexpressed in PDAC specimens [33]. The same group then used small interfering RNAs (siRNAs) to TRPM7 in human pancreas cancer cell lines and found this halted cell cycle progression, resulting in reduced number of cells in the S and G<sub>2</sub>/M phases [33]. This suggested that upregulation of TRPM7 drives carcinogenesis by promoting cell cycle progression.

Another calcium channel in the melastatin subfamily that has a role in PDAC is TRPM8. Like TRPM7, TRPM8 is overexpressed in human PDAC specimens compared to normal tissues [34]. Using siRNAs to TRPM8, not only was cell proliferation reduced, but there was evidence of replicative senescence. This was confirmed via SA  $\beta$ -gal assays, which showed activation in the TRPM8 deficient cells [35]. The exact mechanism of protein upregulation is still underway but the prognostic implications are significant.

The calcium channels TRPM7 and 8 are upregulated in PDAC, and are associated with increased tumor invasiveness, proliferation, and migration [32, 36-38]. Like chloride channels, these calcium channels could be therapeutic targets of anticancer therapies in PDAC.

### *Potassium Channels*

Potassium channels are one of the most widely studied ion channels in pancreas cancer. They are categorized into four groups: voltage gates (Kv), calcium dependent (KCa), two-pore domain group (K2p), and inward rectifying (Kir) [39]. Two channels that are over expressed in pancreas cancer cell lines are Kir3.1 and KCa3.1 [40-42].

Kir3.1 is found within lymphocytes and in resected human PDAC specimens, found to be overexpressed in 80% of tumor specimens [40]. These findings were confirmed by examining RNA levels using reverse transcriptase polymerase chain reaction. However, when examining clinicopathologic features (metastasis) and protein expression, no significant associations were found [40]. Regardless, this study highlights the importance of potassium channels in PDAC carcinogenesis.

Within the tumor microenvironment, lymphocyte activation is essential in determining how the immune system will respond to cancer. Like Kir3.1, the calcium dependent K-channel, KCa3.1, is found within lymphocytes and can modulate their activity [22]. Examination of protein expression in resected human PDAC specimens, showed overexpression to be associated with advanced cancer stage and shorter survival [22, 43]. Studies examining other calcium activated K-channels in pancreas cancer cell lines have found that in PANC-1 cell lines, which have activating mutations in *K-ras*, there were significantly less functional KCa channels per cell compared to BxPC-3 and MiaPaCa-2 cells (PANC-1: ~200 channels/cell; BxPC-3 ~600 channels/cell; MiaPaCa-2: ~1200 channels/cell) [41]. When these cells were treated with K-channel inhibitors, proliferation of BxPC-3 and MiaPaCa-2 cells

stopped whereas it was minimally affected in the PANC-1 cell line [41]. These findings show how differential expression of K-channels can influence cell proliferation. When mRNA evaluation of KCa channels in resected human PDAC was performed, 89% of specimens had upregulation. Compared to the findings from pancreas cancer cell lines (BxPC-3, MiaPaCa-2, and PANC-1), in human specimens, there is overexpression of KCa channels and these could be possible therapeutic targets.

Another voltage gated potassium channel, Kv11.1 (rapid delayed rectifier) was also examined in human PDAC. Immunohistochemical examination of Kv11.1 in 78 PDAC tissue samples found overexpression in tumors compared to the surrounding normal pancreas [44]. When examining clinical features, Kv11.1 overexpression was associated with poor differentiation, higher T-stage, and lymph node positivity [44]. mRNA levels of Kv11.1 was evaluated in human pancreas cancer cell lines and found to be higher compared to non-pancreas cancer cells. In order to examine the mechanism, siRNA silencing of Kv11.1 was undertaken and showed slower cell proliferation in PANC-1 cell lines with higher cell cycles arrest at G1 and greater amounts of apoptosis [44]. Kv11.1 is known to be involved in reorganizing f-actin in PDAC and promoting cell migration [45]. Tumor injection models performed in BALB/c nu/nu mice with si-RNA silenced Kv11.1 found there were significantly lower tumor weights and metastatic nodules in the silenced group [44].

One of the most exciting areas of investigation are the role of specific mitochondrial potassium channels in the development of pancreas cancer. Of these, the voltage dependent potassium channel, Kv1.3, has been studied the most. These topics, as well as the role of mitochondrial Kv1.3 in cancer, will be specifically addressed in other articles within this issue.

## Clinical Trials in Pancreas Cancer

Although there are no specific ion channel inhibitors being examined in clinical trials for PDAC, one promising area of study is use of specific mitochondrial inhibitors. The mitochondria plays an essential role in cell physiology and is home to numerous ion channels located in the inner and outer mitochondrial membranes [46, 47]. Its role in carcinogenesis is becoming increasingly apparent and is the focus of an ongoing clinical trial.

The novel protein CPI-613 acts by inhibiting pyruvate dehydrogenase and  $\alpha$ -ketoglutarate dehydrogenase complexes, thus altering mitochondrial energy metabolism in tumor cells [48, 49]. CPI-613 was evaluated in a phase 1 clinical trial for patients with metastatic pancreas cancer and was found to have an objective response rate of 61% and complete response rate of 17% [48]. Currently there is an ongoing phase 3 randomized control trial (NCT03504423) of CPI-613 with modified FOLFIRINOX vs FOLFIRINOX in patients with metastatic pancreas cancer [49]. The data supporting this trial show that targeting the mitochondria in pancreas cancer can result in dramatic responses and further investigations of specific ion channels within the mitochondria may show tremendous promise.

## Conclusion

Intracellular ion channels play an integral role in the process of oncogenesis and only recently are studies beginning to show how they are involved in the "Hallmarks of Cancer". Pancreas cancer remains a challenging malignancy to treat due to resistance mechanisms developed by the cancer and paucity of effective therapeutic targets. However, ion channels present a novel area of investigation and with better understanding of tumor biology, may provide an alternative and effective treatment for pancreas cancer.
